Dispute Shield: AI Build Log

Author: Shreyansha Ranjan (ISB)

Project: a pre-dispute prevention agent for online sellers, delivered as a clickable prototype, a one-page note and a 90-second demo video.

This file contains no API keys, credentials, private data or proprietary information. All data in the prototype is synthetic. Public sources are linked at the end.

1. AI tools and models used

- **Claude Sonnet 5.5 (Anthropic)**, used in the claude.ai chat interface for research, ideation, critique, prototype code, document drafting and video scripting.
- **Tools available inside the chat:**
  - Web search and page fetch, used for product research and source checking.
  - A code sandbox (Node.js, Python, headless Chromium through Playwright, ffmpeg, LibreOffice), used to test the prototype, record the demo video and check page length.
  - Document and page publishing tools, used to produce the Word and PDF one-pager and to host the prototype.
- No other AI tools were used. No API keys were needed. The prototype is a static HTML file and calls no AI model or external API.

2. Key prompts, workflows and agent setup

Setup. One assistant in a single long conversation. No multi-agent system. The product is designed to run as an agent in Razorpay's Agent Studio, but that setup is a design in the note and not a running integration.

Workflow, in six loops:

1. **Frame.** Share the challenge brief and ask for the track explained and a plan.
2. **Research.** Ask the assistant to read Razorpay's public Agent Studio, Agentic Dashboard, dispute and payment link documentation, and report which ideas already exist.
3. **Stress test.** Ask for two or three options, each scored against the evaluation criteria, with novelty and build effort added as separate columns.
4. **Build.** Ask for the prototype, the note and the video from a written specification, then iterate on feedback after each version.
5. **Verify.** Ask for every public claim to be re-checked against its source page, and for code, page length and video frames to be tested before delivery.
6. **Package.** Export the note to PDF, record the video, write the voiceover and this log.

Representative prompts (paraphrased from the conversation):

- "Explain the track to me and what I can do about it."
- "Shortlist two or three problem options and stress-test each against the criteria."
- "I want something novel, simple to implement, with no overlap with existing Razorpay agents. Check the documentation."
- "Did you check this idea against the Agentic Dashboard?"
- "Is the persona and MVP good enough? Should they go in the one-pager?"
- "Mention data, sources and assumptions carefully."
- "The video and voiceover are too quick. Make them more infographic and focus on the core value."

3. One AI output I corrected, and why

The output. While justifying a cards-first scope, the assistant said a market report showed credit cards increasingly used for higher-value purchases in India.

What happened. I asked for data, sources and assumptions to be stated carefully. The assistant re-fetched each cited page. The "higher-value purchases" statement in the report referred to other markets. For India the report said UPI-type methods carry about 75% of e-commerce volume and domestic cards are the fastest-growing method.

The correction. The claim was removed. The note now says the card segment is narrower than total volume, and treats the link between cards and higher order values as an assumption.

Why it mattered. An unsupported claim about India's payment mix would have weakened the segment argument for any reader who knows the market.

Other corrections:

- The first option list included dispute response, subscription recovery and cashflow forecasting. Research showed these already exist as Razorpay agents, so they were dropped.
- The first demo video had a caption bug: the caption element shared an id with the refund cap field in the prototype. It was found by inspecting video frames and fixed.
- Scene timing in the video drifted late because of how the recorder handled time. The capture method was changed and each scene was checked against its schedule.

4. What AI did versus what I decided or built

AI did:

- Read and summarised public product documentation and public data.
- Generated and compared candidate problems.
- Wrote the prototype code, the one-pager and the video, and tested them in a headless browser.
- Drafted the voiceover script and this log.

I decided:

- The track, and which candidate problems to drop after the overlap check.
- To prioritise pre-dispute prevention, with unpaid payment link recovery as the fallback.
- To start with cards and defer UPI to a second phase.
- That every figure must be labelled as sourced, assumed or synthetic.
- To add a persona, an MVP definition, the value to Razorpay and the sources to the note.
- Interface changes: clickable overview cards, a compact flow diagram, removal of header labels, a Data Sources tab.
- To slow the video and focus it on the core value.

Not done yet. I have not interviewed sellers. The persona and the current workaround remain assumptions, and the note says so. I did not write the code or documents by hand. My role was direction, selection and review.

5. Known limitations, risks and verification steps

Limitations

- All orders, risk scores and dispute probabilities in the prototype are synthetic and illustrative. No model is trained.

- Chargeback rate, success fee, minutes per dispute and cost per hour are assumptions.
- No public chargeback rate for Indian merchants was found, so the 1% ratio is assumed.
- The prototype was tested in a headless browser, not on physical devices.
- The video has captions and no audio. A voiceover script is prepared separately.

Risks

- Refund and exchange messages could be read as discouraging a refund the customer is owed. The design never delays a refund that is owed, and money steps need merchant approval.
- Customer messaging needs consent and an approved channel, which is not verified.
- Access to Shiprocket fields and use of cross-merchant dispute history depend on Razorpay data policy and are not verified.
- Language models can state unsupported claims, as in the correction above.
- Razorpay's launch press release speaks of settling disputes before they escalate. Whether any current agent already scores orders before a dispute should be checked again before relying on the gap.

Verification steps taken

- Each public claim in the note was checked against its source page: the 120-day chargeback window and remittance holds, the 2025 helpline complaint figures, the Agent Studio agent list, the Agent Studio connectors, and the UPI share of e-commerce volume.
- An overlap check against Razorpay's public documentation removed ideas that already exist.
- Prototype behaviour (tab navigation, clickable cards, filter counts, approvals) was tested in a headless browser, with no script errors.
- Page length was checked by rendering the one-pager to PDF.
- Video frames were inspected at set times against the intended schedule.
- Every figure in the note is tagged as sourced, assumed or synthetic.

Time saved (guesstimate, not measured)

Estimated manual effort is about 40 hours, against about 21.5 hours with AI, so about 18 hours saved (46%), with a range of 15 to 25 hours. Manual hours are my assumptions for a first-time builder working alone. AI-assisted hours include time to review and fact-check output. The studies below measured single tasks with earlier tools, and gains in practice are smaller once checking is included, so the range is kept wide.

Stage	Manual (assumed)	With AI (estimate)
Research and overlap checks	8 h	5 h
Ideation and scoring	4 h	2.5 h
Evidence and sources	5 h	3 h
Prototype build and iterations	14 h	6 h
Note and AI log	5 h	3 h
Demo video and script	4 h	2 h
Total	40 h	21.5 h
